

Estimating the effects of parasites on the maintenance of sex

Sang Woo Park and Ben Bolker
McMaster University, Hamilton, Ontario, Canada

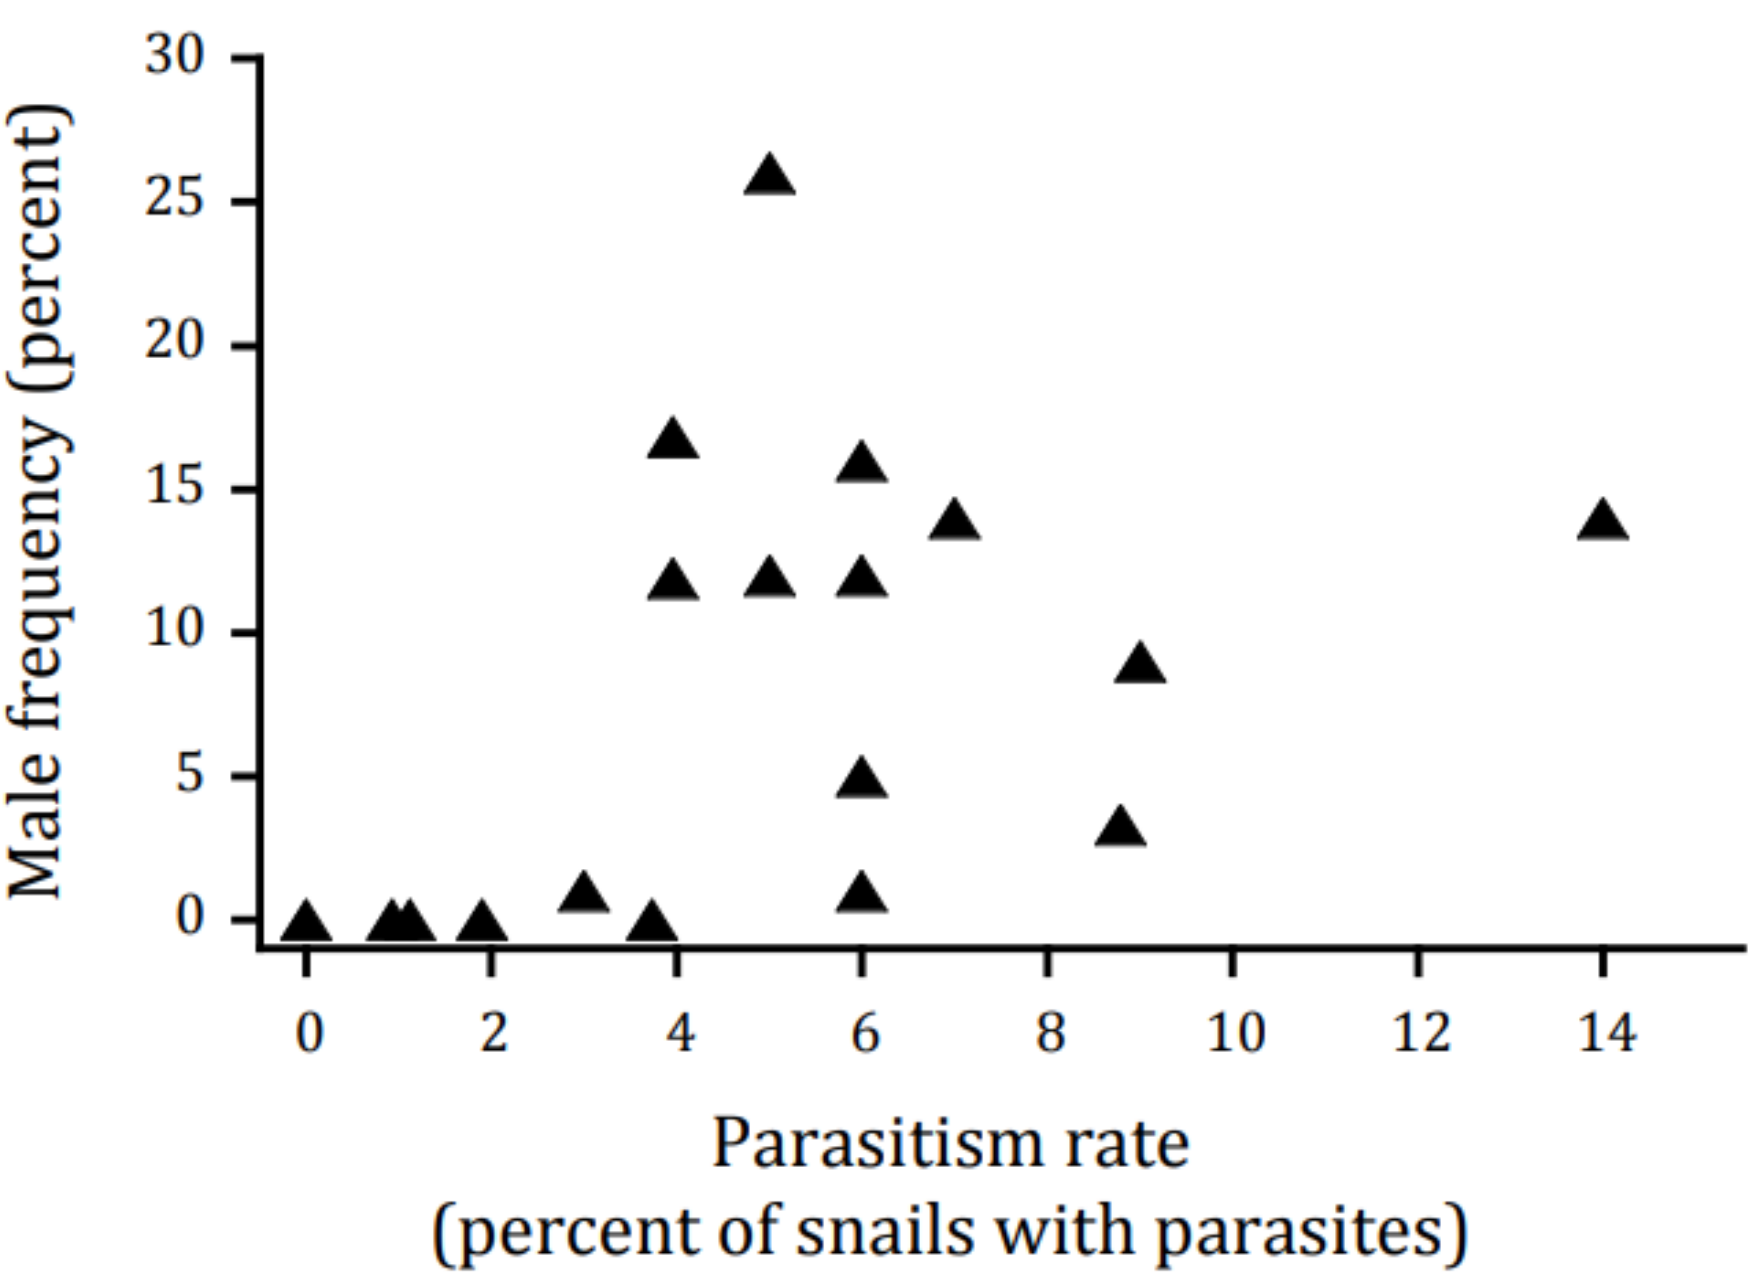

Summary

Why must **sexual reproduction** persist in nature given its **twofold cost**? The **Red Queen Hypothesis** predicts sexually reproducing individuals to overcome the cost of sex by escaping infection more easily under strong parasite selection. Here, we tried to quantify the effect of the Red Queen and perform a power analysis.

Evolution of sex

- **Two fold cost of sex:** (1) cost of producing males and (2) cost of meiosis
- the two fold cost of cost of sex assumes that **all else is equal**
- only 0.01% eukaryotes conform to purely asexual reproduction. How?

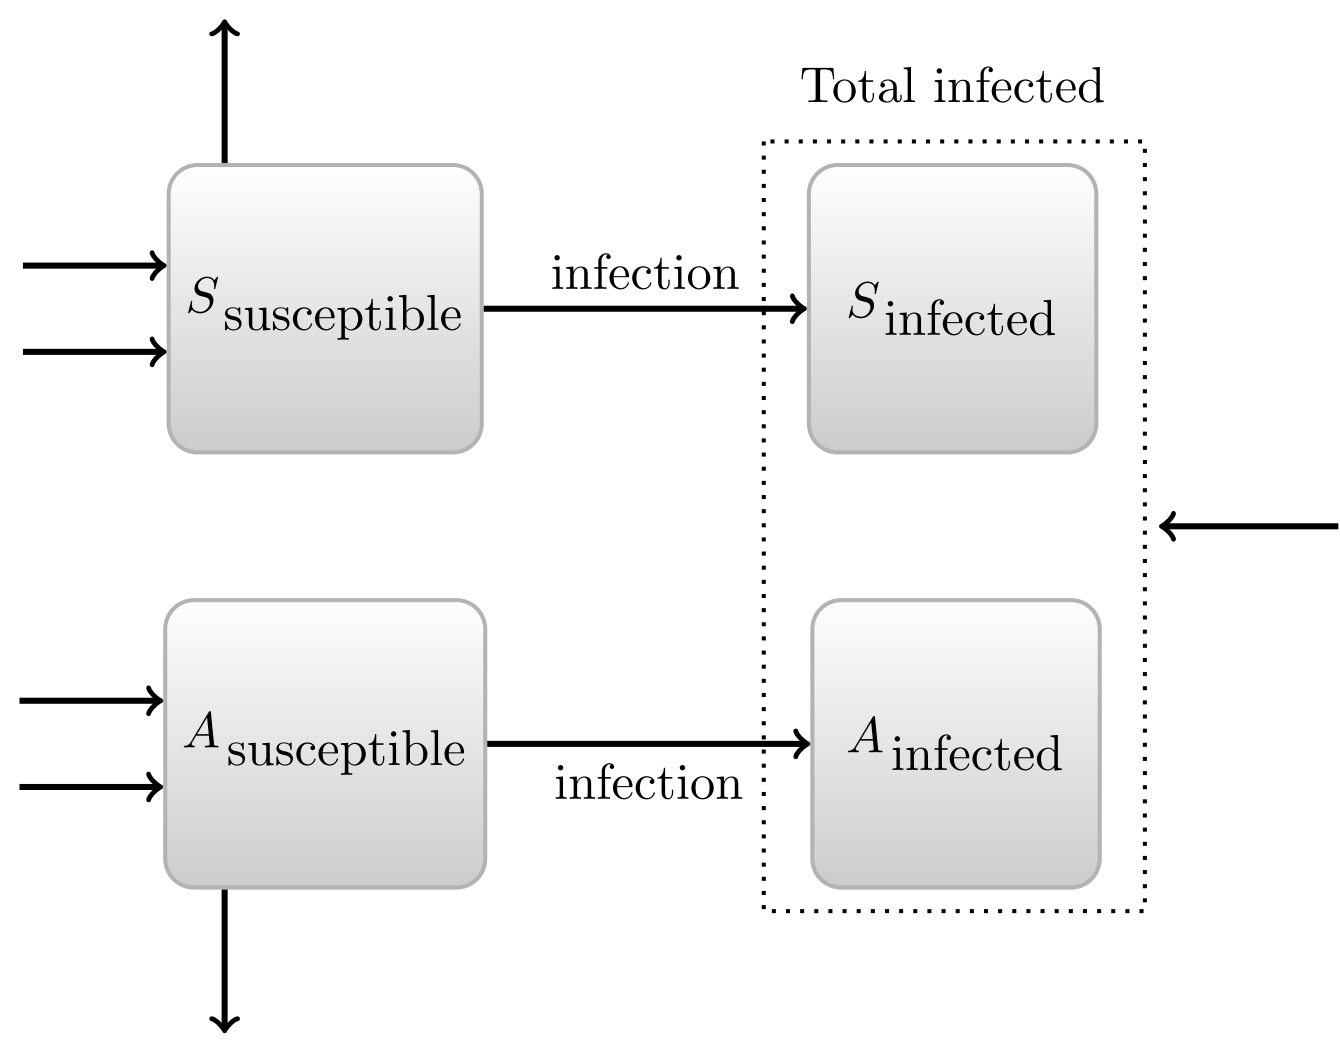

Red Queen Hypothesis

McKone *et al.* [2]

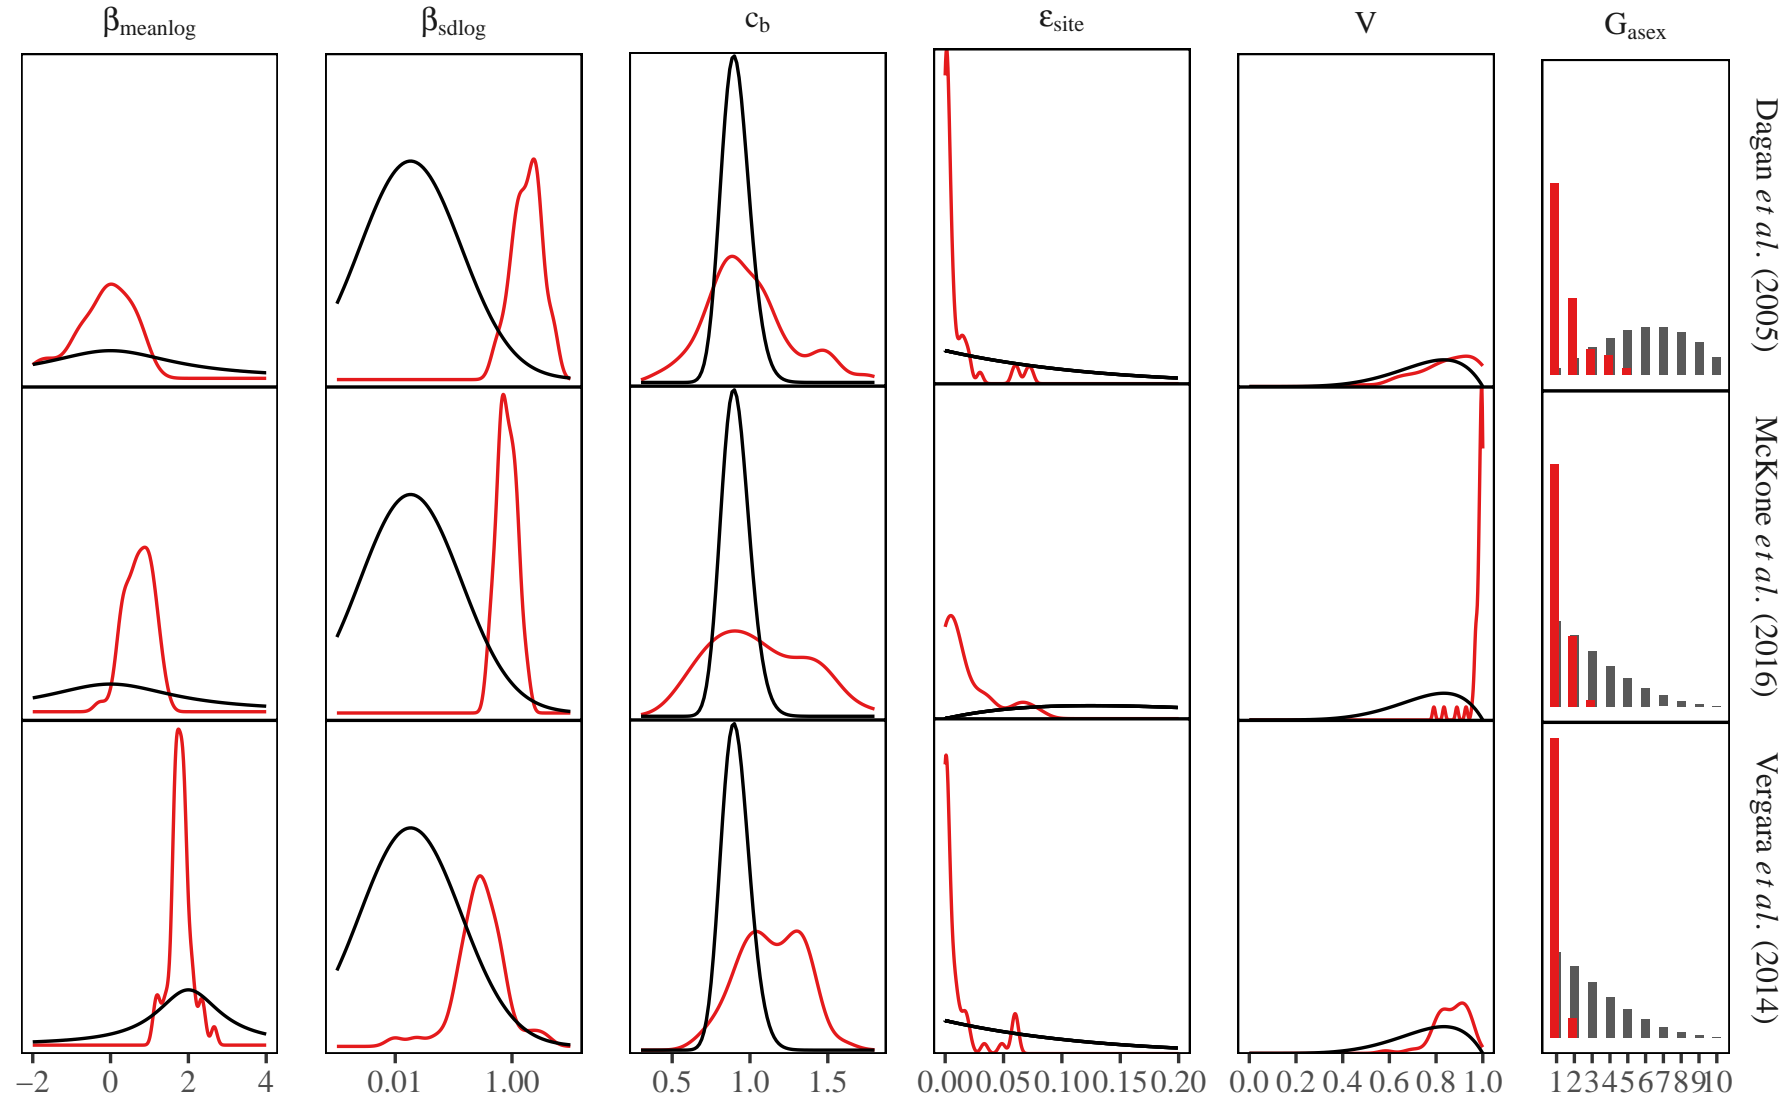

- sexual reproduction creates rare genotypes that can escape infection (**negative frequency dependence**)
- snail population in New Zealand (host for sterilizing trematode infection) is believed to support the hypothesis
- prevalence of sex should be positively correlated with prevalence of infection
- unable to detect any correlation in a similar snail-trematode system [1]

Mathematical model

- diploid hosts with haploid parasites
- obligate sexual v.s. obligate asexual

Approximate Bayesian Computation (ABC)

- Bayes' theorem: $p(\theta|X) \propto p(X|\theta)p(\theta)$
- relies on difference between observed and simulated data rather than explicit likelihood
- Sequential Monte Carlo method allows for efficient approximation of the posterior [3]
- summary statistics compared: mean prevalence of infection/sex and variation in mean prevalence across time/site

Cycles and spatial structure

- lorem ipsum

Conclusion

- Red queen dynamics is hard to measure from spatial data
